

**SOLANUM STOLONIFERUM AND SOLANUM DEMISSUM ACCESSIONS AS  
NEW HOSTS AND RESISTANCE SOURCES TO THE NTN STRAIN OF  
POTATO Y POTYVIRUS**

J. Horváth<sup>1</sup>, G. Kazinczi<sup>1</sup> and Z. Bösze<sup>1</sup>

**ABSTRACT**

Reaction of 34 accessions of *Solanum stoloniferum* and 15 accessions of *Solanum demissum* to the NTN strain of potato Y Potyvirus ( $PVY^{NTN}$ ) were investigated. Out of the wild *Solanum stoloniferum* examined 15 accessions showed hypersensitive resistance and 11 accessions showed extreme resistance to  $PVY^{NTN}$ . The PI. 275247 accession displayed complex, extreme resistance to  $PVY^{NTN}$ , alfalfa mosaic *Alfamovirus*, cucumber mosaic *Cucumovirus* and henbane mosaic *Potyvirus*, therefore this accession is very important in potato breeding for virus resistance. Eight accessions of *Solanum stoloniferum* were systemically susceptible to  $PVY^{NTN}$ . The investigated *Solanum demissum* accessions were equally susceptible to  $PVY^{NTN}$ . Six accessions showed local (chlorotic, necrotic lesions on the inoculated leaves) and systemic symptoms (necrotic spots, veinal necrosis and mosaic on the non-inoculated leaves), too. Nine accessions reacted with systemic symptoms (necrotic spots, veinal necrosis and mosaic) to  $PVY^{NTN}$ . Among the investigated accessions of *Solanum demissum* we have not found resistant (hypersensitive or extreme resistant) plants.

**IZVLEČEK**

**AKCESIJE SOLANUM STOLONIFERUM IN SOLANUM DEMISSUM KOT NOVI  
GOSTITELJI IN VIRI REZISTENCE SEVA NTN KROMPIRJEVEGA Y POTYVIRUSA**

Raziskane so bile reakcije 34 akcij *Solanum stoloniferum* in 15 akcij *Solanum demissum* za sev NTN krompirjevega Y potivirusa ( $PVY^{NTN}$ ). Poleg samonikle (divje) vrste *Solanum stoloniferum* je 15 njenih testiranih akcij kazalo znamenja skrajne hipersenzitivne rezistence, 11 akcij pa je bilo skrajno rezistentnih za  $PVY^{NTN}$ . Akcija PI275247 je odražala kompleksno, skrajno rezistenco za  $PVY^{NTN}$  za lucernin mozaik *Alfamovirus*, kumarni mozaik *Cucumovirus* in mozaik črnega zobnika *Potyvirus*, zato je ta akcija zelo pomembna za žlahtnjenje krompirja za odpornost proti virusom. Osem akcij *Solanum stoloniferum* je bilo sistemično občutljivih za  $PVY^{NTN}$ . Testirane akcije *Solanum demissum* so bile prav tako občutljive za  $PVY^{NTN}$ . Šest akcij je imelo lokalne (klorotične in nekrotične pege na inokuliranih listih) in sistemične simptome (nekrotične pege, žilne nekroze in mozaik na neinokuliranih listih). Devet akcij je reagiralo s sistemičnimi simptomimi (nekrotične pege, žilne nekroze in mozaik) na  $PVY^{NTN}$ . Med testiranimi akcijami *Solanum demissum* niso ugotovljene rezistentne (hipersenzitivne ali skrajno rezistentne) rastline.

**1 INTRODUCTION**

Potato Y Potyvirus ( $PVY$ ) is one of the most important pathogens of potato. The appearance of a new strain of  $PVY$ , which produces severe necrotic rings on the tubers and berries has become highly important in most European countries (Beczner *et al.*, 1984; Radtke, 1984; Weidemann, 1985, 1993; Novák *et al.*, 1986; Dedić *et al.*, 1988; Steinbach and Hamann, 1989; Butorović and Kus, 1989, 1990; Kus 1990, 1995a, b;

<sup>1</sup> Pannon University of Agricultural Sciences, Institute for Plant Protection, H-8361 Keszthely, Hungary

Schiessendoppler, 1990; Le Romancer and Kerlan, 1990, 1991; Nielsen, 1992; Wright, 1992; Le Romancer *et al.*, 1994). This new virus strain belongs to the tobacco veinal necrosis strain group, named PVY<sup>NTN</sup>. Currently, PVY<sup>NTN</sup> is a major virological problem to potato growers and breeders, because it affects cultivars that are either immune or posses high levels of field resistance to PVY (Buturović and Kus, 1989; Weidemann, 1990; Le Romancer and Kerlan, 1992; Van den Heuvel *et al.*, 1994; Pepelnjak, 1995).

As the disease has already reached an epidemic state in some countries (Hungary; Slovenia), identification of sources of resistance gene(s) are of extreme importance. As far as we know, genes are described from *Solanum stoloniferum* (*Nysto*) and *Solanum demissum* (*Nydem*) and found that they gave hypersensitivity to all tested strains of PVY (Cockerham, 1970; Solomon, 1978; Ross, 1986).

Considering that some accessions of the above mentioned wild *Solanum* species as sources of resistance play a highly important role in breeding for virus resistance, we have studied the host-virus relations of some unknown accessions of tuber-bearing *Solanum stoloniferum* and *Solanum demissum* species to PVY<sup>NTN</sup>.

## 2 MATERIALS AND METHODS

Tuber-bearing *Solanum stoloniferum* and *Solanum demissum* accessions free from potato spindle tuber viroid (PSTVd) were mechanically inoculated at a stage of 8-10 leaves with a Hungarian strain of PVY<sup>NTN</sup> (see Beczner *et al.*, 1984). The inoculated plants were symptomatologically checked for infection weekly, then at the end of the 3<sup>rd</sup> and the 6<sup>th</sup> week serological examinations were performed. To check the susceptibility to PVY<sup>NTN</sup> of the accessions of two *Solanum* species double-antibody sandwich ELISA method (DAS-ELISA) was applied using horse-radish peroxidase conjugate (see Clark and Adams, 1977). The color reaction was measured at 492 nm wavelength on Dynatech ELISA reader. Out of the seven inoculated plants of each accessions the highest absorbance value was recorded. Test samples were considered positive if their absorbance values exceeded twice that of the healthy control samples. In symptomless host-virus relations back-inoculation was also carried out to *Chenopodium amaranticolor* and *Nicotiana tabacum* cv. Xanthi-nc indicator plants.

## 3 RESULTS AND CONCLUSIONS

Thirty four accessions of *Solanum stoloniferum* were studied for their reactions to PVY<sup>NTN</sup> (Table 1). According to the results of examinations 15 accessions were found to be hypersensitive resistant (local chlorotic and/or necrotic lesions with leaf drop) to PVY<sup>NTN</sup>. Eleven accessions showed extreme resistance or immunity. Neither the inoculated nor the non-inoculated leaves showed symptoms and the virus could not be detected by serological and biological tests. Eight susceptible accessions of *Solanum stoloniferum* reacted with systemic vein clearing, veinal necrosis, mosaic and in some cases with total necrosis to PVY<sup>NTN</sup>. It is interesting to mention that three accessions of *Solanum stoloniferum* showed complex, extreme resistance to alfalfa mosaic *Alfamovirus*, AMV (PI. 255525, 275245, 275247), cucumber mosaic *Cucumovirus*, CMV (PI. 255548, 275247, 498005) and henbane mosaic *Potyvirus*, HeMV (PI. 275247, 498005, 498007). The PI. 275247 accession displayed complex, extreme resistance to PVY<sup>NTN</sup>, AMV, CMV and HeMV, therefore this accession is very

important in potato breeding for virus resistance (see Horváth and Wolf, 1992, 1995; Bősze *et al.*, 1996).

The reaction of *Solanum demissum* accessions to PVY<sup>NTN</sup> are summarized in Table 2. Six accessions showed local (chlorotic and/or necrotic lesions) and systemic symptoms (necrotic spots, veinal necrosis, mosaic) too. Another nine accessions reacted with systemic symptoms. The investigated 15 accessions of *Solanum demissum* were equally susceptible to PVY<sup>NTN</sup>. Among the investigated accessions of *Solanum demissum* no resistant were found to PVY<sup>NTN</sup>.

#### 4 ACKNOWLEDGEMENTS

We are grateful to J. Bamberg and R. E. Hanneman, Potato Introduction Station, Sturgeon Bay, Wisconsin USA, for sending the seed samples of *Solanum* species. Thanks are also due to Miss K. Molnár for her technical assistance.
